Project ALOHA - a PASSCAL field experiment

A mixed mode PASSCAL/GSN field experiment - Project ALOHA (Arrays for Lithosphere Observations in HAwaii) was carried out in Hawaii, beginning July 19, 1990, to collect digital seismic waveform data from local and teleseismic events. The experiment was supported by NSF. The "local" portion of the experiment using PASSCAL instruments ended December 11, 1990. The main goal of the project is to use converted and reflected seismic waves to map major discontinuities in structure beneath Mauna Loa's southeast flank. During the experiment, we used 16 sets of PASSCAL RefTek instruments, included Data Acquisition Subsystem (DAS), Disk Record Subsystem (DRS), Omega clock, Exabyte Tape Record Subsystem (TRS), and EPSON set up terminal, with 10 sets of 3-component S-13 sensors, four L4-3D seismometers, two CMG3-ESP (Guralp) broadband sensors, and several L4 sensors borrowed from HVO (Hawaiian Volcano Observatory). Two sets of GPS (Global Positioning System) Pathfinder were also used to determine the coordinates for the stations of the ALOHA arrays.

Locations of ALOHA Arrays

We set up four seismic arrays (26 stations) on the Southeast flank of Mauna Loa and one array (5 stations) on the south flank of Kilauea. Our PASSCAL arrays were set up with 4 to 6 three-component digital instruments separated 1 to 2 km in each array. In order to carry out a survey of the broadband ambient seismic noise, we also set up 5 stations equipped with broadband sensor CMG3-ESP on several sites in the center of Island of Hawaii and at the basement of HVO. The coordinates of stations are listed in Table 1 in terms of latitude, longitude, elevation and error. We used GSP Pathfinder to obtain 3–D fix for most of stations so long as signals from four healthy satellites are available. However, we have only 2-D fix for a few stations since sometimes there are not enough satellites available. We checked the GPS readings at HVO's 113 Benchmark, the coordinate of which was determined from a USGS 7.5' topographic map, and found that there was a systematic shift. The systematic differences for latitude and longitude are 11.94" and 9.60" , respectively. That is, LAT (USGS map) = LAT(GPS) + 11.94", and LON (USGS map) = LON (GPS) + 9.60". We also checked several stations whose locations are known and obtained the same result. This difference may due to the use of different geodetic reference surfaces for satellites and USGS maps. In order to make coordinates of the ALOHA arrays compatible with those of stations of HVO seismic network, we give coordinates of our stations (Table 1) after correcting for the systematic difference.

Collected Data

The stations of our arrays equipped with only short-period three-component sensors were set up with two data streams: (1) "microearthquake" triggered data stream with 100 sps and 60 second record (10 second record before trigger mark) and (2) "teleseismic" triggered data stream with 10 sps and 900 second record (30 second record before trigger mark). The lengths of LTA and STA are 1 and 60 seconds for both data streams; while trigger ratio STA/LTA are 4 for the data stream 1 and 3 for the data stream 2, respectively. For the stations equipped with broadband sensors, additional data stream of continuous record with 10 (BP6, BP7, BP7a, and PG6) or 20 (HV1, MK1, MK2, ML1, HV2) sps was set up. The lengths of STA and LTA of "teleseismic" triggered data stream for broadband instrument are 5 and 120 seconds, while trigger ratio STA/LTA is 2.5. We refer continuous, "microearthquake", and "teleseismic" data streams as stream 1, 2 and 3. As of December 11, 1990, we have recorded thousands of locatable local earthquakes and moderate numbers of teleseismic events with the instruments. The HVO magnitudes of local earthquakes range from 0.5 to 4.8. Most of local earthquakes were recorded on the data steam 2, with some of them on both data streams 2 and 3. Many long-period volcanic events were recorded on data stream 3. The teleseismic events with magnitude (Ms) $\geq$ 6.0 generally recorded on both triggered data streams. In most cases, Vertical (Z), north-south (N), and east-west (E) component sensors were generally connected with channels 1, 2, and 3; but sometimes, two additional vertical sensors (Z1 and Z2) were connected with channels 4 and 5. In order to compare the performance of the short-period sensor with broadband instrument, a broadband sensor (Guralp) was connected with channel 1, 2, and 3, while a L4-3D seismometer was connected with channels 4, 5, and 6.

Data Arrangement

The data provided to PASSCAL are the result of runs of the program "cluster" on triggered data from individual arrays (with a 2 second window). Thus the data are contained in directories of array name (AN, BP, PG, SF, WG) with "-cluster" suffix, with subdirectories of /year.day, trigger time (/year.day.hour.minute.second), and data stream number (/02 or /03). The data are in the RefTek SEGY format, though some data converted to SAC format may also be present. Preliminary HVO CUSP locations of local earthquakes are provided with the data; note however that HVO times are all in local Hawaii time (GMT minus 10 hours).

Types of Instruments and Other Pertinent Information

The types of instruments at each stations of our PASSCASL-ALOHA arrays are listed in Table 2. This table consists of types of instruments (sensor, DAS, and DRS) and operation period. Other information, such as preamp-gain, Omega clock health condition, trigger ratio, and site condition for each station are summarized in Table 3.

Table 1. Station Locations of ALOHA Arrays

Station	Latitude	Longitude	Elevation(m)	3-D fix error
