## **ABSTRACT**

This report documents the planning and acquisition of an active source seismic experiment in the lower North Island. The **Seismic Array HiKurangi Experiment** (SAHKE) was designed to investigate the physical parameters controlling locking at the plate boundary beneath the southern North Island and characterise slip processes in the key segment of the Hikurangi margin. This 2011 experiment is the second phase of a two-phase seismic survey to study the characteristics of the subduction interface beneath the Wellington – Wairarapa region. 12 borehole explosive sources were distributed along a NW-SE transect stretching from coast to coast (Kapiti to Glendu). The energy was recorded on 835 seismic stations (277 3-component and 558 vertical sensors) deployed at 100 m spacing and 50 m between Kaitoke and Featherston. Additional 3-component seismometers were deployed at each shot point. The shots were detonated during the night time of May 10-11 and May 12-13, between the hours of 9pm and 5 am. The quality of the data recorded was excellent for all shots.

## **KEYWORDS**

SAHKE, Active source, Seismic array, Wellington-Wairarapa Transect, Hikurangi margin, subduction interface, New Zealand.

## 1.0 INTRODUCTION

GNS Science in conjunction with Victoria University of Wellington, the University of Tokyo (Earthquake Research Institute) and the University of Southern California have undertaken the second phase of the **Seismic Array HiKurangi Experiment** (SAHKE) comprising 12 onshore seismic blasts recorded at 835 seismic stations along a transect of the Wellington-Wairarapa region in the lower North Island, New Zealand. The purpose of this project is to produce seismic images of the subsurface of the lower North Island to investigate the physical parameters controlling locking at the subduction interface and the interaction with the faulting systems evident at the surface.

The SAHKE project is split into two phases. The first phase, carried out and completed between November 2009 and April 2010, consisted of 62 portable seismometers deployed as a number of arrays in the Wellington-Wairarapa region (Seward *et al.*, 2010). The sensors primarily recorded energy released by an airgun array towed behind a ship surveying the Pegasus Basin to the south-east of the North Island (Figure 1.1). During the 5 months of deployments, local, regional and teleseismic earthquakes were recorded as well.

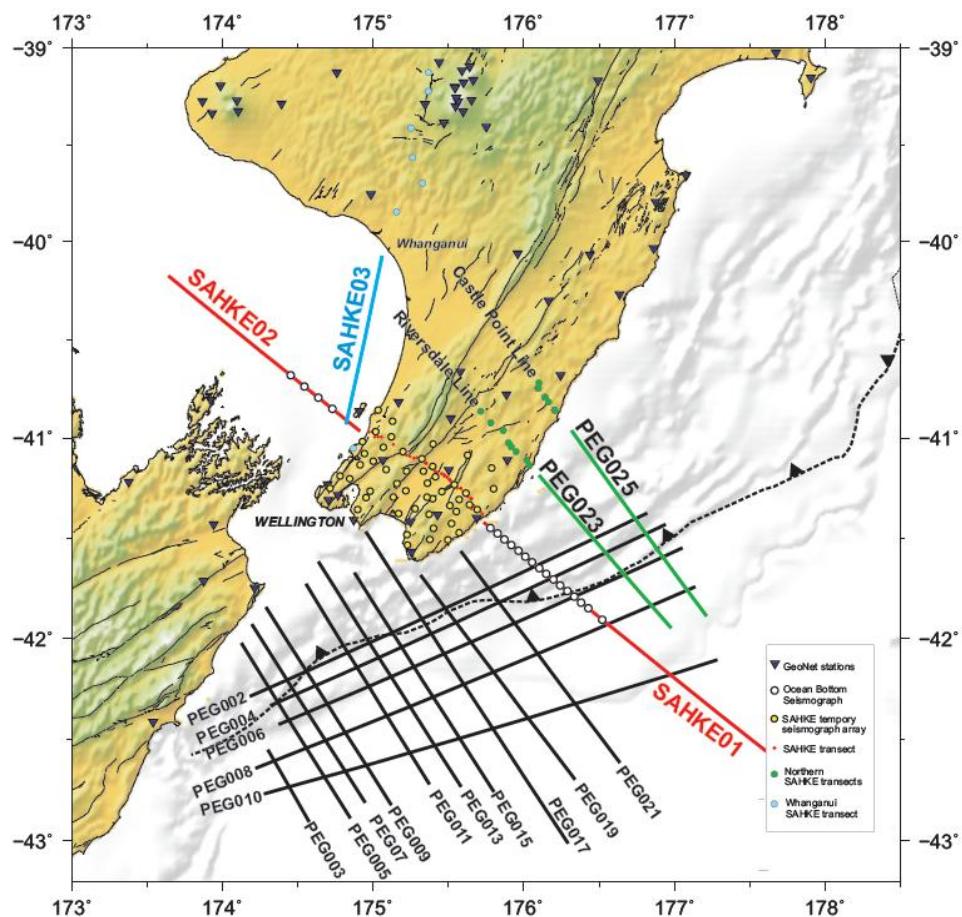

Figure 1.1 Location map showing various elements of the SAHKE phase 1 data acquisition. Black lines show the lines of the PEGASUS survey recorded by the SAHKE ARRAY deployment (stations shown by yellow dots). The red lines are SAHKE01 and SAHKE02 recorded onshore by the TRANSECT deployment indicated by red dots. 20 Ocean bottom seismometers were also deployed during this survey along SAHKE01 and SAHKE02. The blue line shows the offshore Wanganui line (SAHKE03), which was recorded by the associated blue stations onshore (WANGANUI line). The green lines show the northernmost lines of the PEGASUS survey, which were shot in mid-March 2011 and were recorded by two dedicated onshore seismic lines (Castlepoint line and Riversdale line). Inverted blue triangles indicate the locations of permanent stations which are part of the National Network and Wellington regional network monitored by GeoNet.

The second phase of the SAHKE project (SAHKE II) involved the detonation of 12 onshore seismic blasts recorded on 835 seismic stations deployed along a transect stretching from coast to coast (Figure 1.2). This transect array was the same transect line established during SAHKE I which recorded the SAHKE01 and SAHKE02 offshore ship lines. During SAHKE I 32 3-component seismic stations were deployed roughly every 2 km along the transect. SAHKE II densified the transect to 3-component stations every 300m across the island, with vertical component stations spaced every 100m in between. Station spacing was further reduced to 50 m between Kaitoke and Featherston to image the steeply dipping Wairarapa fault. Together with deployments during SAHKE I and the data acquired during SAHKE II this completes the double-sided onshore-offshore transect of the lower North Island.

This report documents the permitting, drilling, shot loading and firing, instrument deployment, data acquisition and archiving during SAHKE II. A summary of the 7-month project is given in Table 1.1.

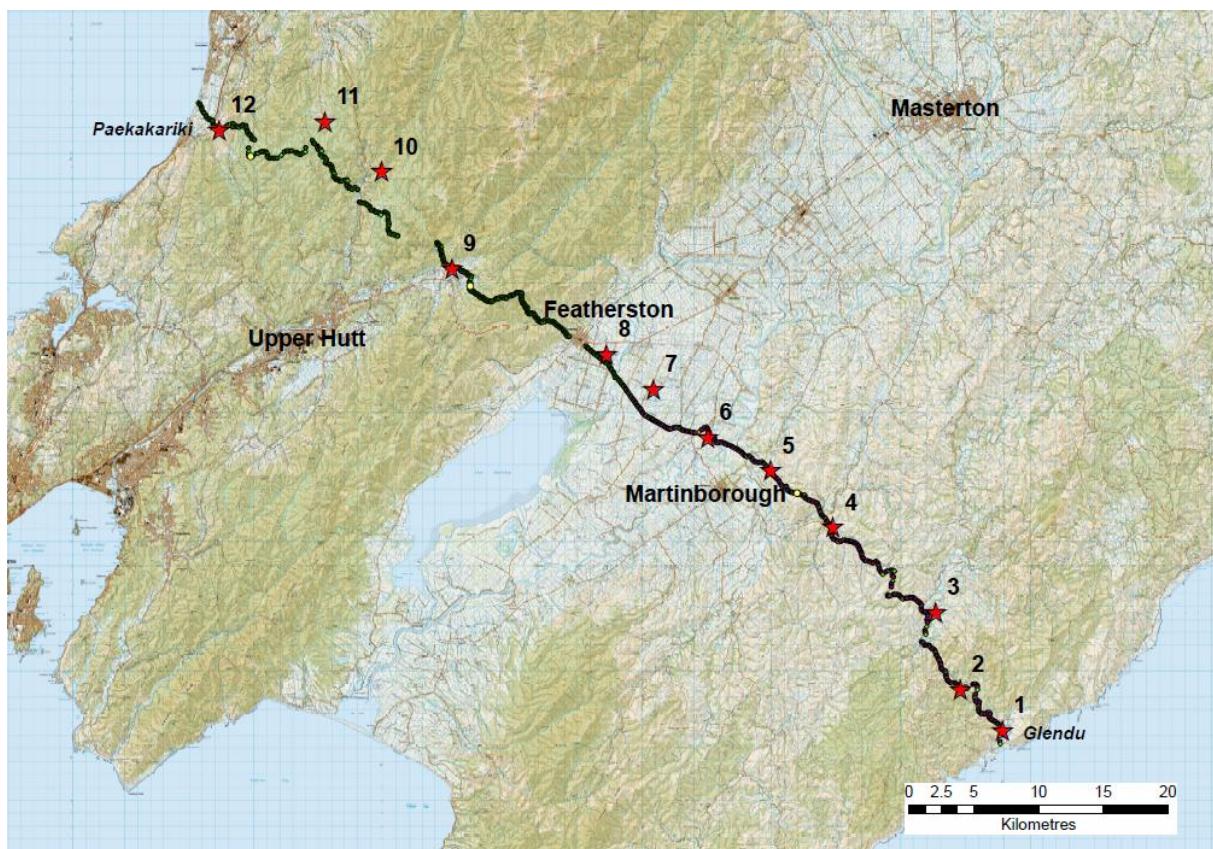

Figure 1.2 Map showing the location of the seismometers (spaced 50-100m along the dark line) deployed during SAHKE II, and the (numbered) red stars show the locations of the 12 borehole seismic sources. Yellow circles indicate the positions of 3 RT130 collocated seismic stations.

## 1.1 TECTONIC SETTING OF THE SOUTHERN NORTH ISLAND

The Wellington region lies at the southern end of the Tonga-Kermadec-Hikurangi subduction zone. It forms part of the westward subduction of thick and bathymetrically elevated oceanic Hikurangi Plateau (Pacific Plate) beneath the Australian Plate, that initiated 20 – 25 Ma ago (Ballance, 1976). In the southernmost North Island, the contemporary oblique plate convergence of ~42 mm/yr can be resolved into ~30 mm/yr of margin-orthogonal motion and ~28 mm/yr of margin-parallel motion (Beavan *et al.*, 2002). The margin-orthogonal component is accommodated by thrust faulting and related folding in the onshore and offshore parts of the Hikurangi Margin's upper plate. In the southern part of the North Island, this takes place by slip on NE-striking reverse faults and folds that occur in an offshore accretionary wedge, and by slip on the subduction megathrust. However, contemporary GPS data indicate that the subduction interface beneath the Wellington region is currently interseismically coupled (locked) over a 90–110 km wide zone perpendicular to the strike of the margin (Wallace *et al.*, 2009). The margin-parallel component of plate motion is accommodated by (1) dextral-slip on the NNE-striking faults of the North Island Dextral fault belt (NIDFB), including the Wellington and Wairarapa faults (e.g. Beanland, 1995, Mouslopoulou *et al.*, 2007, Van Dissen and Berryman, 1996), (2) clockwise vertical-axis rotation of eastern parts of the North Island (e.g. Nicol *et al.*, 2007, Rowan and Roberts, 2008, Wallace *et al.*, 2004), (3) strike-slip on active ENE-striking structures in Cook Strait (such as the Boo Boo Fault), and (4) oblique-slip on other NE-striking offshore faults, including the subduction megathrust which has accommodated a large proportion (>80%) of Neogene and Quaternary crustal plate boundary convergence (Nicol and Beavan, 2003, Nicol *et al.*, 2007). Seismicity data suggest that faults of the overriding plate, including the Wairarapa Fault, intersect the subduction megathrust at depths of 20–30 km beneath the southernmost part of the North Island (Reyners, 1998, Beavan and Darby, 2005).

The wedge of accreted sediment in the southernmost part of the Hikurangi margin is imaged using seismic reflection data, as a thick (> 3 km) but narrow (<80 km wide) prism that

encroaches onshore but widens to the north (Barnes *et al.*, 2010, Davey *et al.*, 1986, Henrys *et al.*, 2006, Lewis and Pettinga, 1993). Earthquake records of conversions of P to S waves from the plate boundary suggest that these low-velocity sediments remain on top of the subducting plate and may be metamorphosed into schistose facies as they descend beneath the western regions (Bannister *et al.*, 2007, Savage *et al.*, 2007). The accretionary wedge comprises a backstop of Mesozoic greywacke rocks and pre-existing passive margin sediments, that range in age from mid Cretaceous to Palaeogene and have been thrust faulted and back tilted since 25 Ma (Lewis and Pettinga, 1993). These rocks, deposited on the active margin of Gondwanaland, are now exposed in the Wellington region (Begg and Johnston, 2000) and along the axial ranges of the North Island. Intervening slope basins on the margin comprise Miocene to Recent trench-fill turbidite sediments overlying the interplate décollement. Correlation of the seismic stratigraphy with published stratigraphy of the Hikurangi Plateau sedimentary sequence (Davy *et al.*, 2008) constrains the ages and stratigraphy of the Mesozoic and Cenozoic sequence subducting beneath the décollement (Barnes *et al.*, 2010). This sequence is inferred to include Cretaceous volcaniclastics, pelagic and clastic sedimentary rocks, and late Cretaceous–early Oligocene (70–32 Ma) nanofossil chalks with alternating clays.

In summary, substantial progress has been made over the last decade in our understanding of a diverse range of tectonics and subduction interface processes at the Hikurangi margin (see Wallace *et al.*, 2009). Marine geophysical studies reveal major along-strike changes in the style of tectonism, including along-strike changes from a strongly accretionary environment (southern Hikurangi margin) to subduction erosion (northern Hikurangi margin) (Barker *et al.*, 2009, Barnes *et al.*, 2010, Barnes and Mercier de Lepinay, 1997, Collot *et al.*, 1996, Collot *et al.*, 2001, Davey *et al.*, 1986, Lewis *et al.*, 1998, Lewis and Pettinga, 1993). The change from accretion to erosion is also accompanied by a northward decrease in thickness of sediment on the subducting Pacific Plate (Lewis *et al.*, 1998) and a three-fold northward increase in the rate of convergence at the trench (Wallace *et al.*, 2004). Recent geodetic studies reveal that there are major along-strike variations in the depth to the down-dip limit of the likely seismogenic zone (Wallace *et al.*, 2004, Wallace *et al.*, 2009). The availability of both contemporary and long-term slip measurements and a paleoseismic record for the southern Hikurangi Margin provides a superb opportunity to address questions for the along-strike heterogeneity of kinematic behaviour at subduction zones worldwide. The SAHKE project aims to understand the frictional properties and geometry of the subduction interface beneath the southern segment of the Hikurangi Margin. Results will be compared to similar studies completed along other segments of the margin (e.g. Henrys *et al.*, 2003, Sutherland *et al.*, 2009) and to studies of other subduction zones - and ultimately, make predictions of earthquake behaviour along the margin.

## **2.0 BOREHOLE SEISMIC SOURCES**

### **2.1 LOCATION DETERMINATION**

The location of the SAHKE transect line was primarily chosen for its accessibility by road and track perpendicular to the strike of major upper crustal faults and along the orthogonal component of motion for the subducting Pacific Plate. Shot point locations were sought in open spaces, where shaking of nearby residences, buildings, and other structures would be minimised. Proximity to unstable landforms was also taken into consideration. Regions of farmland and forest estates were ideal for our needs, as they mostly had good access track, security gates and distances from buildings. In addition, the shot points also needed to be accessible by a drill rig and an explosive loading vehicle in all weather conditions.

Once sites were found and written consent granted by landowners / land users (Appendix 1-Table A1.2), the district councils were consulted over consent requirements for this project (see section 2.2).

### **2.2 PERMITTING AND CONSENT**

The project was discussed with the Greater Wellington Regional Council (GWRC) regarding permits and consent requirements. They required no formal consenting process for this project.

The transect line crosses 3 districts within the Wellington region. The consent needs for each of these districts were discussed with each district council (Kapiti Coast District Council (KCDC), Upper Hutt City Council (UHCC) and South Wairarapa District Council (SWDC)). Proposed locations for the drill sites were also registered with “BeforeUdig” to ensure than no underground surfaces would be disturbed. Only KCDC required a formal consent application for earthworks (see Appendix 2).

Most boreholes were located on private properties with the landowners’ written permission. One site was situated on Department of Conservation (DOC) land and required a “low impact, research and collection permit” and another was located on Wellington Regional Council Parks and Forestry property which also required a “low impact collecting and research permit”. Both applications and permits can be found in Appendix 2.

Local Iwi were also consulted on drill site locations. Only *Te Runaga o Ati Awa ki Whakarongotai* requiring being on site when site 12 was drilled. Other Iwi’s required notification if any historic artefacts were uncovered during drilling and specified that all drilling operations were to be halted in such circumstances. No historic artefacts were uncovered.

### **2.3 DRILLING OF BOREHOLES**

Drilling of the boreholes was planned for the month of February 2011. Honnors Welldrillers Ltd were contracted to drill the 12 seismic boreholes and started at site 7 on January 25<sup>th</sup> 2011. Boreholes were drilled by a truck-mounted drill rig (Figure 2.1) which used either an Ecentrix Odex system with a down hole hammer or a top drive casing hammer drilling system, depending on the local geology. Initial geological assessments (Appendix 3; Table A3.1) were made from geological maps and site visits.

Figure 2.1 Photo (a) shows the drill rig using its top drive casing hammer drilling system; (b) shows the 8in steel casing with a drill bit extension inside; (c) shows the Eccentric Odex drill bit.

All boreholes were completed by March 20<sup>th</sup> 2011 after a few complications that hindered the progress of drilling.

### **2.3.1 Drilling specifications**

Each borehole was drilled to the following specifications:

1. All boreholes to be 200mm (8in) in diameter,
2. All boreholes to reach a vertical depth of 50m,
3. All boreholes to be fully cased with steel casing and be provided with suitable security, for example, capped with a lockable cap,
4. Casing must be well coupled to surrounding ground (anchored when necessary) to avoid blowing out of casing,
5. The casing must protrude above the surrounding ground and appropriate steps taken at the casing exit point to prevent entry of surface water.

### **2.3.2 Drilling methods**

Depending on the local geology at each site, different methods were used to drill the boreholes. The drilling techniques used for each hole are described below.

**Shotpoint 1:**

Ecentrix Odex Style; Down hole hammer with top casing hammer assistance; Air drill to clear hole.  
Fully cased to 48.3m.

Start date: 15/02/2011  
Completion date: 18/02/2011

Figure 2.2 Site 1

**Shotpoint 2:**

Ecentrix Odex Style; Down hole hammer with top casing hammer assistance; Air drill to clear hole.  
Fully cased to 48.0m.

Start date: 10/02/2011  
Completion date: 15/02/2011

## 2.4 BOREHOLE EXPLOSIVES SPECIFICATIONS

Each borehole was loaded with explosives to the following specifications:

1. Boreholes were filled with 500kg of Centra™ Gold explosive emulsion with the exception of shot 7 and 8 where 350kg was used.
2. All boreholes were top primed with 3 seismic booster each 500g (Pentholite) together with detonators.
3. Explosives were sealed within the blast hole by crushed stone. The borehole access was locked in order to prevent any direct access to the detonation wires. The detonator wire was protected to avoid damage.

Figure 2.14 Loading of shot hole 11. The MMU truck used to transport explosive emulsion.

Emulsion was delivered to each site by a special purpose vehicle (Mobile Manufacturing Unit, MMU). Limitation to access for 2 sites meant that Senatel™ solid explosives were used instead.

Boreholes were loaded between the 3<sup>rd</sup> and 5<sup>th</sup> of May, 2011. Detonation of the explosives was completed by Orica at night between the 10-11<sup>th</sup> and 12-13<sup>th</sup> May, 2011. Table 2.1 summarises borehole shot times and explosive types.

Table 2.1 Shot summary information

## 3.0 SEISMOMETER DEPLOYMENT

### 3.1 LOCATION DETERMINATION

The transect line runs from coast to coast over an 80 km profile from Glendu Rocks in the east to Paekakariki in the west. The transect line follows established roads and tracks to cross the island allowing access by vehicle, with the exception of a couple of areas which required access by foot. One of these areas was through dense bush, which had a peat floor of up to 2 m thick. It was decided that the data quality that would result from such poor coupling was not worth the amount of time and effort it would take to deploy in this region, which resulted in a 2 km gap in the resulting data set.

A straight line profile was assumed which ran in line with the offshore profile lines (SAHKE01 & SAHKE02) shot during SAHKE I (Seward *et al.*, 2010). The profile was divided by 50m spacing between points. These points were then orthogonally projected onto the accessible roads and tracks in the proximity. Seismic stations were distributed every 100m (i.e. every 2<sup>nd</sup> point) across the island, with a densification to every 50m in the centre (between the 2 main active faults).

### 3.2 INSTRUMENTS

1300 "Texan" seismometers (REFTEK RT125) were provided by IRIS/PASSCAL and 277 "Lunchbox" seismometers (HAKUSAN LS8200SD) were provided by ERI, University of Tokyo. For the SAHKE deployment, 835 of the Texan instruments were used as 3 component seismometers connected to 3C sensors (Figure 3.1). The timing of the ERI instrument is corrected automatically by a built-in GPS receiver which keeps its accuracy within 1 ms. During deployment of the ERI instrument, its status of recording including GPS clock, and geophone connection and orientation is also automatically checked and displayed by a Light Emitting Diode.

Figure 3.1 (a) photo of "Texan" seismometer attached to a vertical component sensor; (b) Photo of 3 "Texan" seismometers connected to a 3 component sensor (Black – Vertical, Blue – North, Yellow- East); (c) Photo of the ERI "Lunchbox" seismometers connected to a vertical sensor.

Three REFTEK RT130 seismometers (Figure 3.2) were also deployed and collocated at a 3C Texan site in each region. The collocation of these instruments may provide some insight into the time drift associated with the Texans as the RT130 have continuously updated GPS clocks. The Texan instruments were time stamped both prior to deployment and on collection to account for any time drift that may have occurred during deployment (Table A5.2).

Figure 3.2 (a) REFTEK RT130 (b) 3 component sensors (3C) attached to RT130 collocated with the 3C sensor connected to 3 single Texan instruments.

### 3.3 INSTRUMENT PROGRAMMING

Both the Texan and ERI instruments were programmed to record continuously for 6 or 8hr time periods during the nights of May 9 – 14, 2011. The Texans were set to record for a time period of 6 hours the first night, 8 hours for the nights of 10-13, and an additional 6 hours on the 14<sup>th</sup>. Table 3.1 lists the programming parameters used for both instrument types.

Table 3.1 Programmed recording times for the instruments deployed.

Date	Instrument	Start time		End time	
		local time	UTC	local time	UTC
May 9	Texan	22:55	2011:129:10:55:00	04:55	2011:129:16:55:00
	ERI	21:00	2011:129:09:00:00	05:00	2011:129:05:00:00
May 10	Texan	20:55	2011:130:08:55:00	04:55	2011:130:16:55:00
	ERI	21:00	2011:130:09:00:00	05:00	2011:130:05:00:00
May 11	Texan	20:55	2011:131:08:55:00	04:55	2011:131:16:55:00
	ERI	21:00	2011:131:09:00:00	05:00	2011:131:05:00:00
May 12	Texan	20:55	2011:132:08:55:00	04:55	2011:132:16:55:00
	ERI	21:00	2011:132:09:00:00	05:00	2011:132:05:00:00
May 13	Texan	20:55	2011:133:08:55:00	04:55	2011:133:16:55:00
	ERI	21:00	2011:133:09:00:00	05:00	2011:133:05:00:00
May 14	Texan	22:55	2011:134:10:55:00	04:55	2011:134:16:55:00
	ERI	21:00	2011:134:09:00:00	05:00	2011:134:05:00:00

The Texan instruments were programmed to record at a sample rate of 250 Hz (4 ms sample rate) and a gain of 32 with file lengths of 1 hr. The ERI LS8200SD recorded at a sample rate of 250 Hz.

### 3.4 DEPLOYMENT

The 3C sensors were deployed every 300m along the transect, while the vertical component sensors were distributed in-between with 100m spacing. The spacing of sensors was densified between Kaitoke and Featherston to 50m spacing between stations and a 3C site every 150m. The deployment was split into 3 segments (Figure 3.3): Kapiti, which covered the western part of the transect, from Kapiti Coast to the Akatarawa Forest; Kaitoke, which covered the central densified region, between Kaitoke and Featherston; Wairarapa, which covered the eastern side of the transect. The majority of the single component sites deployed in the Wairarapa region were the ERI “Lunchbox” seismometers.

All 3-component instruments were aligned to magnetic North when deployed.

Table 3.2 Timeline for SAHKE II during May 2011. Red indicates nights when shot were detonated, while pink indicate the time period that the instruments were programmed to record.

Detonate Shots																						
Collect instruments																						
Clean up																						

The deployment of the seismometers was relatively rapid, taking approximately 15-20 mins for a station. Since daylight hours were limited during this time of year, field teams were based within the regions they were working. Six field teams were based in the Wairarapa and had the most traveling to do to get to their deploying area. The field teams were split into those deploying the ERI instruments and those deploying the 3C Texan sites. All teams averaged between 20 – 30 sites per day. Three teams were based in Kaitoke to deploy the densified region of the transect. Teams worked together deploying both 1C and 3C and managed to get 30 – 50 sites done per day. The teams based in Kapiti had the region of most difficult access and needed to deploy on foot or with the aid of a quad bike delivering instruments. Three teams were deployed in this region and averaged 20 sites per team per day. The locations of both the Texans and ERI stations were determined using hand-held GPS using NZTM coordinates.

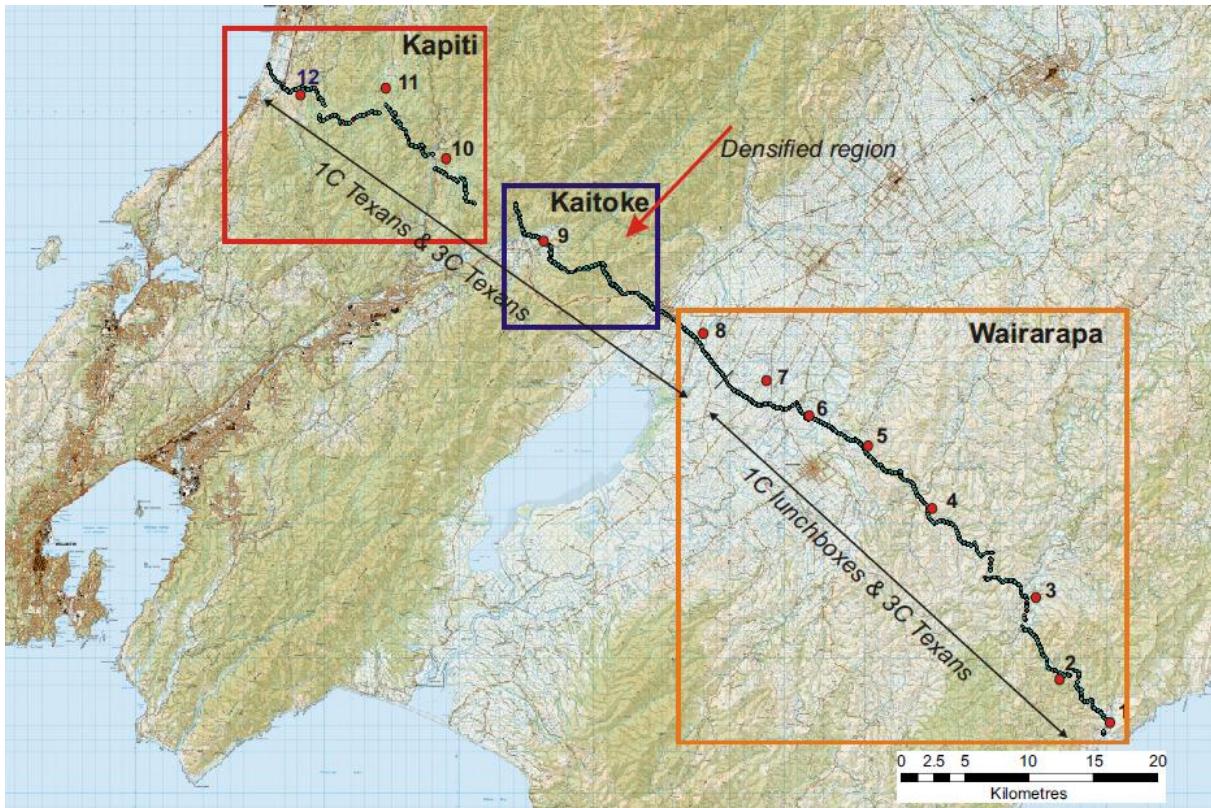

Figure 3.3 Map showing the deployment regions.

The three Reftek-130s were collocated with three 3C Texan stations. One Reftek-130 was deployed in each region at stations with good ground coupling. Several vertical component Texan stations were also collocated with the 1C ERI instruments. Additional vertical component stations were deployed at shots 3, 7, 8 and 9. These stations had several houses in proximity, and the additional instruments were used to monitor ground roll associated with the shot. Instrument locations and details are given in Appendix 4 (Table A4.1).

### 3.4.1 Weather

Weather during SAHKE II deployment, shooting, and pick up was mostly mild. Temperatures on most days were about 10-15°C. The average daily high for the month of May, 2011, was 13.7 °C.

The autumn period is generally dominated by low pressure systems that sweep from west to east across the lower North Island bringing intense rain for short periods. A period of rain at the beginning of May preceded our first scheduled installation day causing some delays in accessing farm tracks. In addition 2 shot hole sites could not be reached by the MMU truck and were therefore loaded with re-packed explosives. Another front passed during the day that we had allocated to shot firing. We delayed firing over the night of 11 May to allow the front to pass.

On 15 May, heavy rain caused flooding in Wellington, with SH2 closed by a slip in Hutt Valley (see Figure 3.4). We were able to delay pick up of instruments in the ranges till this rain had passed and were not hampered in getting instruments out of the field.

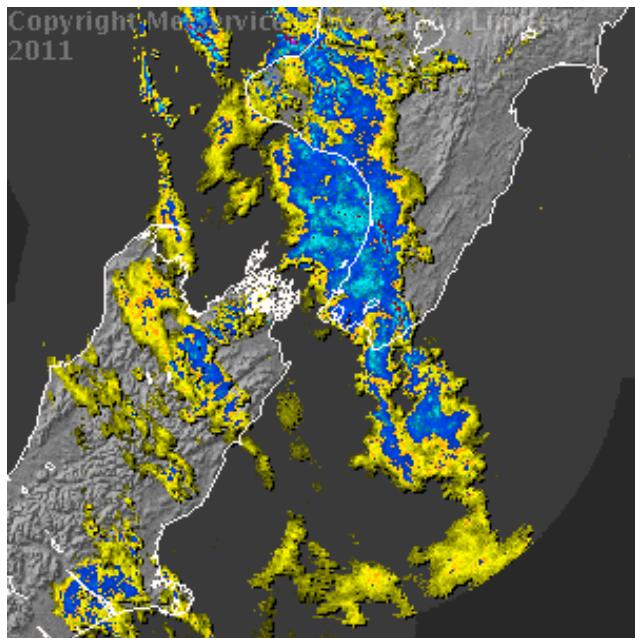

Figure 3.4 Radar map of the Wellington region during 15 May. The light blue colours indicate the most intense rainfall. The passing front caused only slight delays in collecting seismometers.

## 4.0 DATA

### 4.1 DETONATION OF THE SHOTS

Shots were detonated at night, between the hours of 9pm and 5am. This time period is chosen as it is generally quiet and the seismic signals can be detected more readily. All instruments were programmed to record during this time period (Table 3.1). Since the instruments were recording continuously, the time of the shot triggering was dependant only on the shot firing team. The triggering of the shot was done with the use of the GPS clock that sends a pulse to the detonator on the minute mark.

Figure 4.1 Shot firing trigger system.

#### 4.1.1 Shot firing system

The shot firing system consists of four parts: the Spectrum TM4 GPS clock, a PIC microcontroller, a fast optical relay, and an SIE blasting machine. The operation of the complete system is as follows:

1. the operator connects the shot-firing wires from detonators to the blasting machine;
2. the GPS clock system is turned on and the user waits until the time has initialised;
3. after initialisation has been achieved, the clock will output a trigger pulse at every minute mark;
4. the operator waits until approximately 20 seconds before the minute mark and presses the “charge” button on the blasting machine;
5. approximately one second before the minute mark the operator presses the “fire” button;
6. at the minute mark the GPS clock system outputs a signal to the blasting machine, which in turn discharges the internal capacitor through the shot line into the detonators.

The Spectrum TM4 uses the information transmitted by GPS satellites to determine not only its position, but also an estimate for the current time as defined in the GPS time system. This is internally adjusted to UTC. Once initialised the TM4 can maintain a close estimate for UTC even when GPS satellites are not available, for example, under tree cover. It achieves this by using an ovenized quartz oscillator and by estimating the clock’s drift through comparison with the GPS time estimates. The TM4 can be programmed over its serial port interface to output TTL-level pulses through its signal lines. These pulses can be programmed to occur at any time, and there are a range of duration and repeat options. In this case, to simplify the system for the operator, it was decided to use a pulse on every minute mark.

To simplify the system further, instead of using a laptop computer to manually program the TM4, the programming of the TM4 is performed automatically by a circuit based around a PIC microcontroller. As soon as the system is turned on the PIC microcontroller repeatedly interrogates the TM4 over its serial port to determine whether the time it is calculating is valid. When the time is valid then the PIC will program the TM4 to output firing pulses at each minute mark. The PIC will continue to check the TM4 to make sure the system is operating correctly. Additionally, because the TM4 does not have its own display, the PIC operates an LCD display. The display shows the date, time, the number of GPS satellites, whether the time is valid, and whether the pulse has been programmed.

The output signal directly from the TM4 is only TTL level and is not sufficient to operate the mechanical relays in the blasting machine. Also, when interfacing digital logic to any external device it is advisable to have robust isolation. Isolation is especially important in this case, where not only is the back EMF from the relay an issue, but also the possibility of inadvertently coupling high-voltage from the capacitor discharge into the signal line. For this reason the TM4 output is connected to a fast optical relay, which is in turn connected to the blasting machine.

The blasting machine is a typical capacitor discharge system. When the charge button is pressed the internal capacitor is charged using a high voltage (~120V) to approximately 1.5J. In its normal operating mode, when the fire button is pressed the capacitor is connected to the shot firing line to fire the explosives. The blasting machine also has another operating mode, which if selected means that the shot will only fire if both the fire button is pressed and an external switch has been operated. This external switch connection in this case is connected to the optical relay in the GPS clock system.

Specifications of the shot firing system suggest that the electrical discharge should occur within 10-ms of the programmed time. This is primarily the delay in the mechanical relay of the blasting machine. However, in practice, the delay in firing was much less than 10-ms.

During each of the SAHKE shots an array of three vertical geophones, and a single 3C seismometer connected to REFTEK 130 seismographs were used to validate shot times. The geophone array was laid out nearby and parallel to the shot firing line. As a consequence the induced voltage is clearly seen on some of the seismograms. The electrical discharge occurs 3 – 5ms after the programmed time. The explosion is recorded approximately 11ms after the programmed time, although initiation undoubtedly occurs much earlier.

#### 4.2 DATA MERGING

The mix of REFTEK and ERI instruments posed several merging problems. Although all of the playback systems produce SEG-Y data tapes, the header files were different for each system. Merging the data required extensive processing to archive the data in SEG-Y format in a manner that would be useful for subsequent data analysis (see Table A6.1). The SEG-Y standard requires that all the data have common sampling rates and lengths with coherent indexing within the SEG-Y trace headers.

Data were ordered primarily by shot and secondarily by channel. Channel number is based on station location and on station components. Channel numbering starts in the west and is increased eastward by each trace.

#### 4.3 DATA QUALITY

The quality of the data recorded was good for all shots. The energy from each shot was recorded clearly at each seismometer from coast to coast. Figure 4.2 shows a preliminary shot gather from shot 9, near Kaitoke. The data quality is excellent. Clear direct arrivals are visible on all traces and distinctive reflections from the probable top of slab ( $P_{\text{slab}}P$ ).

There are several instruments that had problems during the deployment. These stations are listed in Appendix 4 (Tables A5.1 & A5.2).

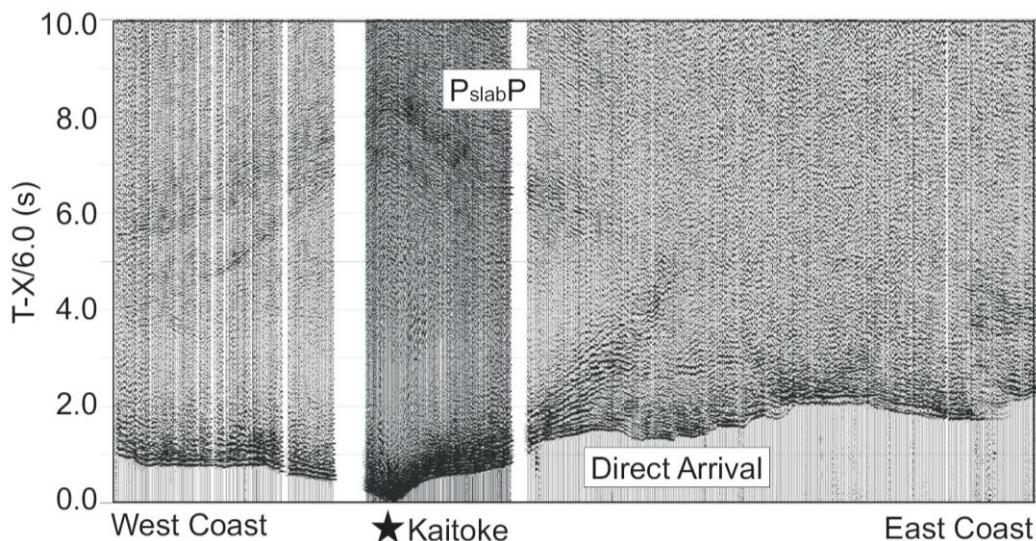

Figure 4.2 Shot gather from Kaitoke source (shot 9). Each trace is one seismogram location. Gaps in the data plot correspond to areas where stations were not deployed, due to access issues (Akatawara Ranges and Featherston). Trace spacing is 100 m across the profile, with the exception between Kaitoke and Featherston where instruments were spaced 50 m apart.

## 5.0 OUTREACH

During the experiment, and afterwards, efforts were made to inform the public about the projects. Prior to the start of the projects, landowners and councils were given information flyers that outlined the objectives and plans of the experiment. District councils were kept informed as the project evolved. Landowners were informed of the project, what we would be doing and when we would be on their property. Public notices were published in all local newspapers (Figure 5.1). Table 5.1 lists the contacts with the media.

## 6.0 ACKNOWLEDGEMENTS

The New Zealand Foundation for Research Science and Technology and the Japanese Science and Technology Agency, and the National Science Foundation, USA, funded this work. We are grateful to the individual land owners, Greater Wellington Regional Council, Transpower, Department of Conservation and regional Iwi who kindly allowed us onto their land. The IRIS/Passcal instrument pool and the Earthquake Research Institute provided the instruments. Staff at GNS Science (Gary Gosper, Lianne Brejnakowski, Brett Gilles, Dave Hewitson, Sharryn Duggan and IT Support Staff), helped at critical times to ensure that this project ran smoothly. A more complete list of organisations and people that assisted in this experiment is given in Appendix 1.

	Lloyd Pledger	- Kapiti field team
	Caroline Hall	- Kapiti field team
	Jess Johnson	- Kaitoke field team
	Sapthala Karalliyadda	- Kaitoke field team
	Brook Keats	- Kaitoke field team
	Katrina Jacobs	- Base logistics
<b>ERI, University of Tokyo</b>	Hiroshi Sato	- Principal Investigator - Wairarapa field team
	Eiji Kurashimo	- Wairarapa field team
	Yoshitaka Nakayama	- Wairarapa field team
	Toshio Haneda	- Wairarapa field team
	Takeshi Iidaka	- Wairarapa field team
	Tatsuya Ishiyama	- Wairarapa field team
	Shigehiro Kitamura	- Wairarapa field team
<b>University of Southern California</b>	David Okaya	- Principal Investigator - Wairarapa field team
	Panxu Zhang	- Wairarapa field team
	Yilei Rong	- Wairarapa field team
	Won Joon Song	- Kaitoke field team
<b>PASSCAL</b>	Lloyd Carothers	- Texan Technician - RT130 & shot point deployment
	Greg Chavez	- Texan Technician - RT130 & shot point deployment

## **APPENDIX 2: PERMIT AND CONSENT APPLICATIONS**

### **A 2.1 Resource consent for Kapiti Coast District council**

Resource Consent for Earthworks was needed for the two boreholes that were proposed to be drilled within the Kapiti Coast region. An application was submitted to Ross Goodman at Kapiti Coast District Council in December 2010, and was approved in January 2011 (see CD Appendix 2 – Kapiti Coast).

In addition to the application written permission was required from the landowners, other people who may be affected by the work, and the local Iwi. In total, four notices of written approval were included in the application.

### **A 2.2 Consent application for the Department of Conservation**

A Low Impact, Research and Collection Application was required by the Department of Conservation (DoC) for borehole site 12, which was situated on DoC owned land (see CD Appendix 2 – Department of Conservation). The application also included the deployment of seismometers in this region and on part of the Pylon Track (near Featherston).

### **A 2.3 Consent application for Greater Wellington Regional Council**

A Low Impact Collecting and Research Permit was required for the drilling of borehole 9 on Greater Wellington Regional Council land (See CD Appendix 2 – Forest & Parks). The permit was also required for the deployment of seismometers in the Akatarawa Forest Park and Kaitoke Park. After some discussion with Owen Spearpoint in the GWRC head office, to further discuss our proposed work, a permit was given that covered access to Queen Elizabeth Park on the Kapiti Coast as well as those regions applied for.

## APPENDIX 3: DRILL LOGS

This section provides additional information regarding the geology and drill logs at the boreholes sites. Table A3.1 shows the preliminary geological information at each proposed drilling site as based on the geological maps of New Zealand. Table A3.2 lists the logs recorded by the drilling team during drilling. Figure A3.1 illustrated the geological cross sections of the boreholes.

Table A3.1 Initial geology and hazard assessment of proposed borehole sites

Site	Location	Geology	Access	Potential Hazards
1. Glendu	Glendu -41.38154 , 175.73104	Soil layer at top with gravels and unconsolidated silt beneath	Good access Flat paddock adjacent to gravel road	Close to river Barn 500m away <i>Alternative site available</i>
2. Pahoa	Pahoa rd -41.35234 , 175.68497	River gravels, sand and silts overlying hard sandstone	Good access Paddock adjacent to gravel road	Close to river Close to public gravel road
3. Hinakura	Hinakura -41.30807 , 175.66516	Gravels, sandstone and siltstone	Good access Flat paddock off well maintained main farm track	Hill side terrain
4. Longbush	Near Longbush rd / Hinakura rd junction -41.23991 , 175.56505	River bed sediments of sand and silt, minor gravel overlying limestone	Good access (potential marsh field after rain) Paddock off main farm track	500 m from barn Surrounding hill slopes when wet
5. Martinborough	North of Martinborough -41.20963 , 175.51077	Thin soil overlying moderately hard sandstone	Good access Main farm track	Proximity to Martinborough
6. Bidwill Cutting	Featherston / Greytown junction -41.18073 , 175.44689	Gravels	Good track, with steep section	Access issues ?
7. Featherston	Camp road -41.013088 , 175.37747	Gravels	Flat paddock crossings	
8. Rimutaka	Rimutaka Hills YET to be determined	Gravels and hard rock		
9. Kaitoke	Kaitoke / Upper Hutt -41.06834 , 175.20501	Thick gravels overlying greywacke	Good access cross paddocks	Hill side terrain
10. Cloustonville	Akatarawa -41.00772 , 175.13766	Thins soil overlying greywacke	Well maintained Tracks Some steep segments	Hills
11. Menin Reiki	Kapiti / Akatarawa -40.97064 , 175.08489	Thin soil overlying greywacke	Well maintained Forestry tracks	Forestry vehicles
12. Whareroa Farm	Kapiti -40.97671 , 174.98876	Soil/silt overlying greywacke	Good tracks cross paddocks	Public site / DOC land

Table A3.2 Logs from drilling at borehole sites

**Borehole 1:**

Depth (m)	Description
1.00	Top soil
6.00	Gravel
48.3	Mix of papa, mudstone and clay

**Borehole 2:**

Depth (m)	Description
0.30	Top soil
12.00	Brown silt and overburden
16.00	Blue silt and overburden: water bearing
26.00	Brown rubble and rock: water bearing
40.00	Blue clay and stone
48.00	Less but firmer blue clay and stones

**Borehole 3:**

Depth (m)	Description
9.00	Gravel and top soil
50.36	Papa

**Borehole 4:**

Depth (m)	Description
1.50	Brown pan
3.00	Brown silt
28.00	Fine blue silt - dry
50.0	Sandy blue silt: water bearing – very unstable

**Borehole 5:**

Depth (m)	Description
20.3	Brown clay, pan and small stones
50.3	Blue mudstone

**Borehole 6:**

Depth (m)	Description
1.00	Top soil and stones
3.00	Brown Pan
6.50	Brown Gravel – clay bound
8.00	Blue clay bound gravel
15.5	Brown gravel : water bearing
23.0	Blue clay bound gravel
26.0	Brown clay
33.0	Brown clay and stones
50.00	Stiff blue clay

**Borehole 7:**

<b>Depth (m)</b>	<b>Description</b>
0.50	Top soil and stones
18.5	Brown gravel – little water
21.5	Stiff blue clay
25.0	Mix of red and blue gravel : water bearing
26.0	Brown clay
27.5	Blue clay
33.5	Blue clay and stone – little water
39.0	Mix of brown, red and blue clay – stiff and sticky
43.0	Sandy blue gravels : water bearing
50.0	Brown clay bound gravels

**Borehole 8:**

<b>Depth (m)</b>	<b>Description</b>
20.0	Gravel and clay
50.0	Gravel and bands of clay : water bearing

**Borehole 9:**

<b>Depth (m)</b>	<b>Description</b>
16.0	Gravel and clay
18.0	Blue clay
50.42	Blue rock – quite hard

**Borehole 10:**

<b>Depth (m)</b>	<b>Description</b>
6.0	Clay
50.0	Rock: water bearing from 12.5m

**Borehole 11:**

<b>Depth (m)</b>	<b>Description</b>
8.0	Top soil
14.0	Gravel with some water
18.00	Hard brown rock
50.5	Blue rock – very firm at 27m: water bearing from 22m

**Borehole 12:**

<b>Depth (m)</b>	<b>Description</b>
3.0	Top soil and clay
6.0	Gravel and clay
18.0	Gravel and clay
50.2	Rock: water bearing

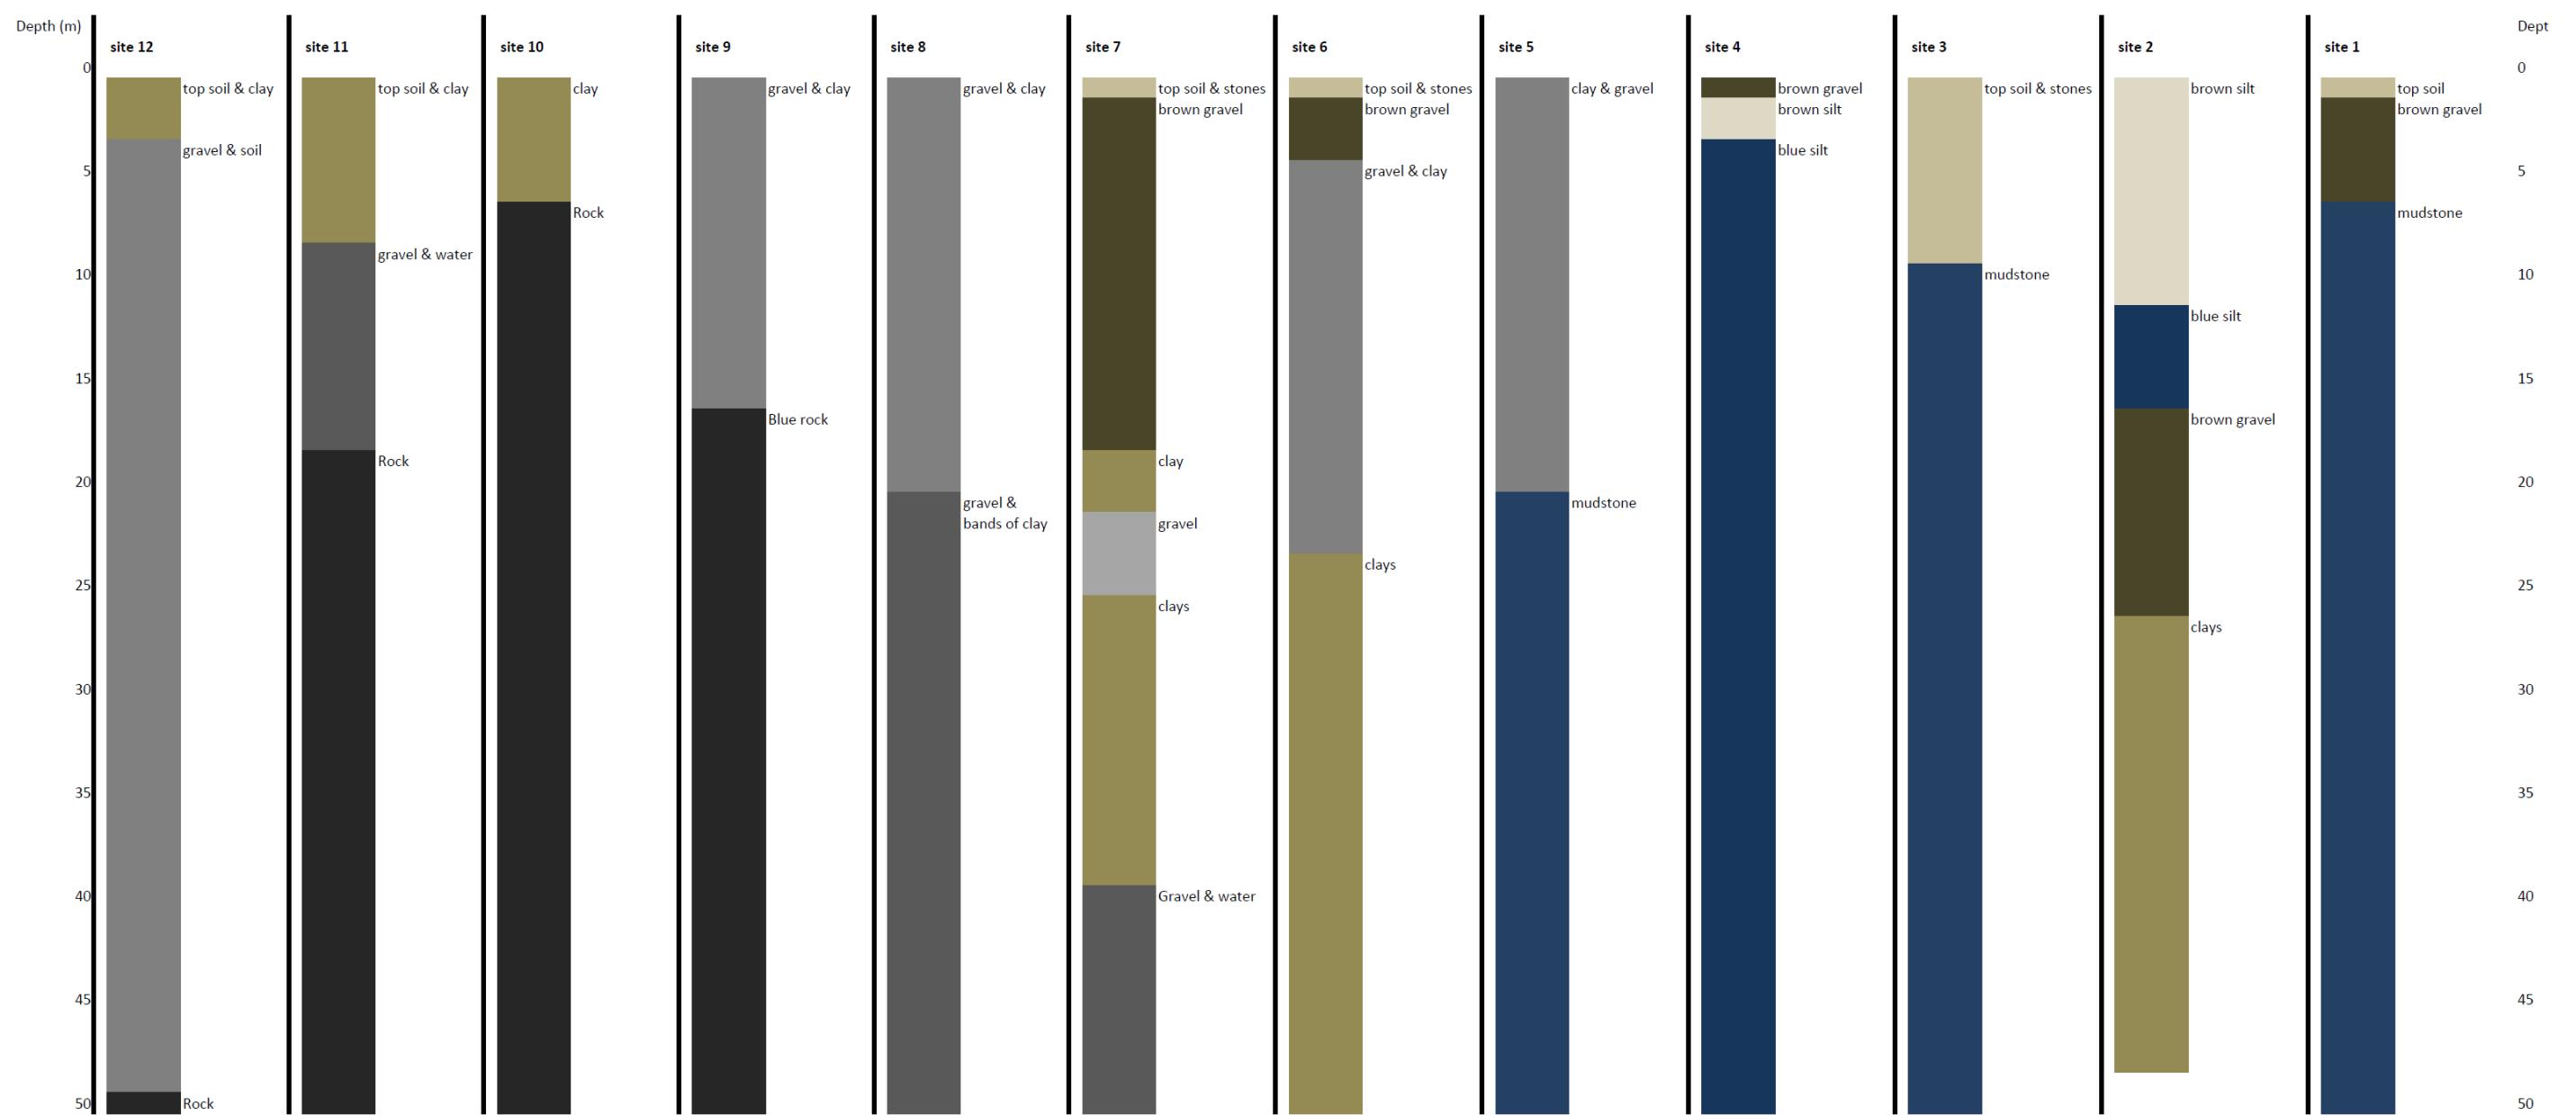

Figure A3.1 Illustration of the drill logs for the 12 boreholes from west (12) to east (1).

## **APPENDIX 4: INSTRUMENT LOCATIONS**

Instruments were deployed roughly every 100m across the lower North Island. The 3C sensors were deployed every 300m along the Transect, while the vertical component sensors were distributed in-between with 100m spacing. The spacing of sensors was densified between Kaitoke and Featherston to 50m spacing between stations and a 3C site every 150m. Table A4.1 lists the locations and serial numbers of the instruments deployed.

Table A4.1 List of seismometers deployed. (Stations in italics are questionable locations due to poor GPS coverage)

SCE – Sample Count Errors – can cause noisy data files. Numbers following SCE indicate which files are affected.

LBV – Low Battery Voltage – causes Texan to shut down in the field, how early is indicated by the size of the memory recovered.

DiF – Disabled in Field – most likely due to low battery, but no proof.

Table A5.3 List of ERI station problems

<b>Station</b>	<b>Component</b>	<b>Serial</b>	<b>Problem</b>
10902	z	01034	Logger did not work – No data
10946	z	06003	disconnected GPS - Time correction was incomplete since 21:00 11/5/2011
11018	z	04010	Logger did not work – No data
11072	z	08010	disconnected GPS - Time correction was incomplete since start
11120	z	01136	Logger did not work – No data
11142	z	07003	disconnected GPS - Time correction was incomplete since 01:00 13/5/2011
11192	z	08001	disconnected GPS - Time correction was incomplete since 21:00 11/5/2011
11324	z	01195	Logger did not work – No data

## APPENDIX 6: SEG-Y HEADERS

Table A6.1 SEG-Y header information. Fields in bold are specific trace header entries for the SAHKE II experiment
